Enzyme subsets: Sets of reactions carrying flux in fixed ratio.

Elementary modes: Minimal, independent pathways in a system

Conserved cycles: Sets of metabolites whose total concentration is fixed.

Technical challenges with large models

Null space: Readily calculated, but can't analyse by inspection.

Enzyme subsets: Not as generally useful compared to small models.

Elementary modes: Impractical.

Conserved cycles: Not as generally useful compared to small models.

Other disadvantages of null-space analysis

- Provides a rather 'unfocussed' view of the system.
- Does not (implicitly) take into account thermodynamics.
- Hard to integrate experimental flux observations.
- Less interpretable for large (genome-scale) models.
- (Still very useful for validation).

Linear programming calculates a specific solution to the equation:

Nv = 0

Subject to some additional information supplied by the user - at least one flux value specified.

◆□▶ ◆□▶ ★ □▶ ★ □▶ → □ → の Q ()

$$\begin{array}{rcl} \min/\max & : & \mathbf{V}_{\text{targs}} & \longleftarrow & \text{objective} \\ \text{subject to} & \begin{cases} \mathbf{N}\mathbf{v} = \mathbf{0} & \longleftarrow & \text{steady state} \\ \max_{i} \geq \mathbf{v}_{i} \geq \min_{i} & \longleftarrow & \text{flux constraints} \end{cases}$$

Typical Objectives:

- Maximise output(s) (need to fix input(s))
- FBA maximise growth rate for fixed input.
- Minimise input(s) (need to fix output(s))
- Minimise *all* reactions (need to fix input(s) and/or output(s))

ヘロン 人間 とくほ とくほ とう

- FBA maximise growth rate for fixed input.
- Minimise input(s) (need to fix output(s))
- Minimise all reactions (need to fix input(s) and/or output(s))

$$\begin{array}{rcl} \min/\max & : & \mathbf{V}_{\text{targs}} & \longleftarrow & \text{objective} \\ \text{subject to} & \left\{ \begin{array}{rcl} \mathbf{N}\mathbf{v} = \mathbf{0} & \longleftarrow & \text{steady state} \\ \max_i \geq \mathbf{v}_i \geq \min_i & \longleftarrow & \text{flux constraints} \end{array} \right. \end{array}$$

Typical flux constraints:

•
$$\min_i = \max_i \neq 0$$
 : flux is fixed

•
$$\min_i = \max_i = 0$$
 : reaction is knocked out.

•
$$\min_i = 0$$
, $\max_i \neq 0$: force irreversible L->R

•
$$\min_i \neq 0$$
, $\max_i = 0$: force irreversible R->L

- Very fast.
- Integrates flux data.
- Easy to reformulate the problem and solve again.
- The reactions in a solution can be extracted from the main model for more detailed analysis.

通 と く ヨ と く ヨ と

• Only provides a single solution.

• Potential for numerical instability (esp. if maximising).

• Potential for multiple optima.

• Choice of the objective is subjective (!)

< 回 > < 回 > < 回 > -

æ

Exploring the optimal space - constraint scanning

- Find a solution.
- Increment one (or more) of the constraints vi
- Solve again.
- Repeat to build up a set of solutions.
- Identify correlated responses in the solution set.

★ E ► ★ E ►

Example - identifying a catabolic core

A study of Salmonella spp.

• Antibiotic challenges generate a stress response.

• This increases the demand for ATP.

 How to identify which reactions will respond to this demand?

Scan over a range of ATP demand fluxes (while synthesising biomass) and identify responding reactions.

minimise :
$$|\mathbf{v}|$$
 \leftarrow objective – min. sum of fluxe
subject to
$$\begin{cases} \mathbf{N}\mathbf{v} = \mathbf{0} & \leftarrow \text{ steady state constraint} \\ v_j = t_j & \leftarrow \text{ output transporters, constant} \\ v_{\text{ATPase}} = J_{\text{ATPase}} & \leftarrow \text{ ATP hydrolysis, varied} \end{cases}$$

イロト イポト イヨト イヨト 一日

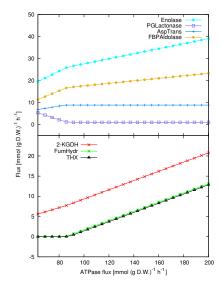

Scan over a range of ATP demand fluxes (while synthesising biomass) and identify responding reactions.

minimise :
$$|\mathbf{V}|$$
 \leftarrow objective – min. sum of fluxes
subject to
$$\begin{cases} \mathbf{N}\mathbf{V} = \mathbf{0} & \leftarrow \text{steady state constraint} \\ \mathbf{V}_{j} = t_{j} & \leftarrow \text{output transporters, constant} \\ \mathbf{V}_{\text{ATPase}} = J_{\text{ATPase}} & \leftarrow \text{ATP hydrolysis, varied} \end{cases}$$
